## IIR 21: Link Analysis

Hinrich Schütze

Institute for Natural Language Processing, University of Stuttgart

2011-12-20

# Overview

- 1 Recap
- 2 Anchor text
- 3 Citation analysis
- 4 PageRank
- 5 HITS: Hubs & Authorities

# Basic crawl architecture

# URL frontier

The URL frontier is the data structure that holds and manages URLs we've seen, but that have not been crawled yet.

# What a crawler must do

## Be polite

- Don't hit a site too often
- Only crawl pages you are allowed to crawl: robots.txt

## Be robust

- Be immune to spider traps, duplicates, very large pages, very large websites, dynamic pages etc

# What any crawler should do

- Be capable of **distributed** operation
- Be scalable: need to be able to increase crawl rate by adding more machines
- We can't index everything: we need to **subselect**.
- **Freshness**: we need to recrawl periodically.
  - Because of the size of the web, we can do frequent recrawls only for a small subset.
  - Subselection problem or **prioritization**
- Duplicates: need to integrate **duplicate detection**
- Spam and spider traps: need to integrate **spam detection**

# Mercator URL frontier

- URLs flow in from the top into the frontier.
- Front queues manage prioritization.
- Back queues enforce politeness.
- Each queue is FIFO.

# Take-away today

- Anchor text: What exactly are links on the web and why are they important for IR?
- Citation analysis: the mathematical foundation of PageRank and link-based ranking
- PageRank: the original algorithm that was used for link-based ranking on the web
- Hubs & Authorities: an alternative link-based ranking algorithm

# The web as a directed graph

- Assumption 1: **A hyperlink is a quality signal.**
  - The hyperlink  $d_1 \rightarrow d_2$  indicates that  $d_1$ 's author deems  $d_2$  high-quality and relevant.
- Assumption 2: **The anchor text describes the content of  $d_2$ .**
  - We use anchor text somewhat loosely here for: the text surrounding the hyperlink.
  - Example: "You can find cheap cars `<a href=http://...>here</a>`."
  - Anchor text: "You can find cheap cars here"

[text of  $d_2$ ] only vs. [text of  $d_2$ ] + [anchor text  $\rightarrow d_2$ ]

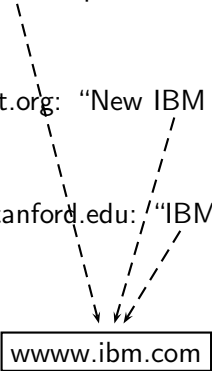

- Searching on [text of  $d_2$ ] + [anchor text  $\rightarrow d_2$ ] is often more effective than searching on [text of  $d_2$ ] only.
- Example: Query *IBM*
  - Matches IBM's copyright page
  - Matches many spam pages
  - Matches IBM wikipedia article
  - May not match IBM home page!
  - ... if IBM home page is mostly graphics
- Searching on [anchor text  $\rightarrow d_2$ ] is better for the query *IBM*.
  - In this representation, the page with the most occurrences of *IBM* is [www.ibm.com](http://www.ibm.com). □

# Anchor text containing *IBM* pointing to [www.ibm.com](http://www.ibm.com)

[www.nytimes.com](http://www.nytimes.com): “IBM acquires Webify”

[www.slashdot.org](http://www.slashdot.org): “New IBM optical chip”

[www.stanford.edu](http://www.stanford.edu): “IBM faculty award recipients”

[www.ibm.com](http://www.ibm.com)

# Indexing anchor text

- Thus: Anchor text is often a better description of a page's content than the page itself.
- Anchor text can be weighted more highly than document text. (based on Assumptions 1&2) □

## Exercise: Assumptions underlying PageRank

- Assumption 1: A link on the web is a quality signal – the author of the link thinks that the linked-to page is high-quality.
- Assumption 2: The anchor text describes the content of the linked-to page.
- Is assumption 1 true in general?
- Is assumption 2 true in general? □

# Google bombs

- A Google bomb is a search with “bad” results due to maliciously manipulated anchor text.
- Google introduced a new weighting function in January 2007 that fixed many Google bombs.
- Still possible: [completely wrong] on Google image search returns picture of Mitt Romney
  - Coordinated link creation by those who dislike the Mitt Romney
- Defused Google bombs: [dumb motherf....], [miserable failure], [evil empire], [dangerous cult]

# Origins of PageRank: Citation analysis (1)

- Citation analysis: analysis of citations in the scientific literature
- Example citation: “[Miller \(2001\)](#) has shown that physical activity alters the metabolism of estrogens.”
- We can view “Miller (2001)” as a hyperlink linking two scientific articles.
- One application of these “hyperlinks” in the scientific literature:
  - Measure the similarity of two articles by the overlap of other articles citing them.
  - This is called [cocitation similarity](#).
  - Cocitation similarity on the web: Google’s “related:” operator, e.g. [related:www.ford.com] □

## Origins of PageRank: Citation analysis (2)

- Another application: Citation frequency can be used to measure the **impact** of a scientific article.
  - Simplest measure: Each citation gets one vote – not very accurate.
- On the web: citation frequency = **inlink count**
  - A high inlink count does not necessarily mean high quality . . .
  - . . . mainly because of link spam.
- Better measure: **weighted** citation frequency or citation rank
  - An citation's vote is weighted according to its citation impact.
  - Circular? No: can be formalized in a well-defined way. □

## Origins of PageRank: Citation analysis (3)

- Better measure: weighted citation frequency or citation rank
- This is basically PageRank.
- PageRank was invented in the context of citation analysis by Pinski and Narin in the 1960s.
- Citation analysis is a big deal: The budget and salary of this lecturer are / will be determined by the impact of his publications! □

# Origins of PageRank: Summary

- We can use the same formal representation for
  - citations in the scientific literature
  - hyperlinks on the web
- Appropriately weighted citation frequency is an excellent measure of quality ...
  - ... both for web pages and for scientific publications.
- Next: PageRank algorithm for computing weighted citation frequency on the web

# Model behind PageRank: Random walk

- Imagine a web surfer doing a random walk on the web
  - Start at a random page
  - At each step, go out of the current page along one of the links on that page, equiprobably
- In the steady state, each page has a **long-term visit rate**.
- This long-term visit rate is the page's **PageRank**.
- **PageRank = long-term visit rate = steady state probability** □

# Formalization of random walk: Markov chains

- A Markov chain consists of  $N$  states, plus an  $N \times N$  transition probability matrix  $P$ .
- state = page
- At each step, we are on exactly one of the pages.
- For  $1 \leq i, j \leq N$ , the matrix entry  $P_{ij}$  tells us the probability of  $j$  being the next page, given we are currently on page  $i$ .
- Clearly, for all  $i$ ,  $\sum_{j=1}^N P_{ij} = 1$

# Example web graph

	PageRank	
$d_0$	0.05	
$d_1$	0.04	
$d_2$	0.11	
$d_3$	0.25	
$d_4$	0.21	
$d_5$	0.04	
$d_6$	0.31	

PageRank( $d_2$ ) < PageRank( $d_6$ ): why?

	$a$	$h$
$d_0$	0.10	0.03
$d_1$	0.01	0.04
$d_2$	0.12	0.33
$d_3$	0.47	0.18

## Link matrix for example

	$d_0$	$d_1$	$d_2$	$d_3$	$d_4$	$d_5$	$d_6$
$d_0$	0	0	1	0	0	0	0
$d_1$	0	1	1	0	0	0	0
$d_2$	1	0	1	1	0	0	0
$d_3$	0	0	0	1	1	0	0
$d_4$	0	0	0	0	0	0	1
$d_5$	0	0	0	0	0	1	1
$d_6$	0	0	0	1	1	0	1

## Transition probability matrix $P$ for example

	$d_0$	$d_1$	$d_2$	$d_3$	$d_4$	$d_5$	$d_6$
$d_0$	0.00	0.00	1.00	0.00	0.00	0.00	0.00
$d_1$	0.00	0.50	0.50	0.00	0.00	0.00	0.00
$d_2$	0.33	0.00	0.33	0.33	0.00	0.00	0.00
$d_3$	0.00	0.00	0.00	0.50	0.50	0.00	0.00
$d_4$	0.00	0.00	0.00	0.00	0.00	0.00	1.00
$d_5$	0.00	0.00	0.00	0.00	0.00	0.50	0.50
$d_6$	0.00	0.00	0.00	0.33	0.33	0.00	0.33

# Long-term visit rate

- Recall: PageRank = long-term visit rate
- Long-term visit rate of page  $d$  is the probability that a web surfer is at page  $d$  at a given point in time.
- Next: what properties must hold of the web graph for the long-term visit rate to be well defined?
- The web graph must correspond to an **ergodic** Markov chain.
- First a special case: The web graph must not contain **dead ends**. □

# Dead ends

- The web is full of dead ends.
- Random walk can get stuck in dead ends.
- If there are dead ends, long-term visit rates are not well-defined (or non-sensical).

## Teleporting – to get us out of dead ends

- At a **dead end**, jump to a random web page with prob.  $1/N$ .
- At a **non-dead end**, with probability 10%, jump to a random web page (to each with a probability of  $0.1/N$ ).
- With remaining probability (90%), go out on a random hyperlink.
  - For example, if the page has 4 outgoing links: randomly choose one with probability  $(1-0.10)/4=0.225$
- 10% is a parameter, the **teleportation rate**.
- Note: “jumping” from dead end is independent of teleportation rate.

# Result of teleporting

- With teleporting, we cannot get stuck in a dead end.
- But even without dead ends, a graph may not have well-defined long-term visit rates.
- More generally, we require that the Markov chain be **ergodic**.

# Ergodic Markov chains

- A Markov chain is ergodic iff it is irreducible and aperiodic.
- **Irreducibility.** Roughly: there is a path from any page to any other page.
- **Aperiodicity.** Roughly: The pages cannot be partitioned such that the random walker visits the partitions sequentially.
- A non-ergodic Markov chain:

# Ergodic Markov chains

- Theorem: For any ergodic Markov chain, there is a unique long-term visit rate for each state.
- This is the **steady-state probability distribution**.
- Over a long time period, we visit each state in proportion to this rate.
- It doesn't matter where we start.
- **Teleporting makes the web graph ergodic.**
- **⇒ Web-graph+teleporting has a steady-state probability distribution.**
- **⇒ Each page in the web-graph+teleporting has a PageRank.**

## Where we are

- We now know what to do to make sure we have a well-defined PageRank for each page.
- Next: how to compute PageRank □

## Formalization of “visit”: Probability vector

- A probability (row) vector  $\vec{x} = (x_1, \dots, x_N)$  tells us where the random walk is at any point.

- Example: 
$$\begin{pmatrix} 0 & 0 & 0 & \dots & 1 & \dots & 0 & 0 & 0 \\ 1 & 2 & 3 & \dots & i & \dots & N-2 & N-1 & N \end{pmatrix}$$

- More generally: the random walk is on page  $i$  with probability  $x_i$ .

- Example: 
$$\begin{pmatrix} 0.05 & 0.01 & 0.0 & \dots & 0.2 & \dots & 0.01 & 0.05 & 0.03 \\ 1 & 2 & 3 & \dots & i & \dots & N-2 & N-1 & N \end{pmatrix}$$

- $\sum x_i = 1$  □

## Change in probability vector

- If the probability vector is  $\vec{x} = (x_1, \dots, x_N)$  at this step, what is it at the next step?
- Recall that row  $i$  of the transition probability matrix  $P$  tells us where we go next from state  $i$ .
- So from  $\vec{x}$ , our next state is distributed as  $\vec{x}P$ . □

## Steady state in vector notation

- The steady state in vector notation is simply a vector  $\vec{\pi} = (\pi_1, \pi_2, \dots, \pi_N)$  of probabilities.
- (We use  $\vec{\pi}$  to distinguish it from the notation for the probability vector  $\vec{x}$ .)
- $\pi_i$  is the long-term visit rate (or PageRank) of page  $i$ .
- So we can think of PageRank as a very long vector – one entry per page. □

## Steady-state distribution: Example

- What is the PageRank / steady state in this example?

## Steady-state distribution: Example

	$x_1$	$x_2$		
	$P_t(d_1)$	$P_t(d_2)$		
			$P_{11} = 0.25$	$P_{12} = 0.75$
			$P_{21} = 0.25$	$P_{22} = 0.75$
$t_0$	0.25	0.75	0.25	0.75
$t_1$	0.25	0.75	(convergence)	

PageRank vector =  $\vec{\pi} = (\pi_1, \pi_2) = (0.25, 0.75)$

$$P_t(d_1) = P_{t-1}(d_1) * P_{11} + P_{t-1}(d_2) * P_{21}$$

$$P_t(d_2) = P_{t-1}(d_1) * P_{12} + P_{t-1}(d_2) * P_{22}$$

# How do we compute the steady state vector?

- In other words: how do we compute PageRank?
- Recall:  $\vec{\pi} = (\pi_1, \pi_2, \dots, \pi_N)$  is the PageRank vector, the vector of steady-state probabilities ...
- ... and if the distribution in this step is  $\vec{x}$ , then the distribution in the next step is  $\vec{x}P$ .
- But  $\vec{\pi}$  is the steady state!
- So:  $\vec{\pi} = \vec{\pi}P$
- Solving this matrix equation gives us  $\vec{\pi}$ .
- $\vec{\pi}$  is the principal left eigenvector for  $P$  ...
- ... that is,  $\vec{\pi}$  is the left eigenvector with the largest eigenvalue.
- All transition probability matrices have largest eigenvalue 1.  $\square$

# One way of computing the PageRank $\vec{\pi}$

- Start with any distribution  $\vec{x}$ , e.g., uniform distribution
- After one step, we're at  $\vec{x}P$ .
- After two steps, we're at  $\vec{x}P^2$ .
- After  $k$  steps, we're at  $\vec{x}P^k$ .
- Algorithm: multiply  $\vec{x}$  by increasing powers of  $P$  until convergence.
- This is called the **power method**.
- Recall: regardless of where we start, we eventually reach the steady state  $\vec{\pi}$ .
- Thus: we will eventually (in asymptotia) reach the steady state. □

## Power method: Example

- What is the PageRank / steady state in this example?

- The steady state distribution (= the PageRanks) in this example are 0.25 for  $d_1$  and 0.75 for  $d_2$ . □

# Computing PageRank: Power method

	$x_1$	$x_2$			
	$P_t(d_1)$	$P_t(d_2)$			
			$P_{11} = 0.1$	$P_{12} = 0.9$	
			$P_{21} = 0.3$	$P_{22} = 0.7$	
$t_0$	0	1	0.3	0.7	$= \vec{x}P$
$t_1$	0.3	0.7	0.24	0.76	$= \vec{x}P^2$
$t_2$	0.24	0.76	0.252	0.748	$= \vec{x}P^3$
$t_3$	0.252	0.748	0.2496	0.7504	$= \vec{x}P^4$
				...	...
$t_\infty$	0.25	0.75	0.25	0.75	$= \vec{x}P^\infty$

PageRank vector  $= \vec{\pi} = (\pi_1, \pi_2) = (0.25, 0.75)$

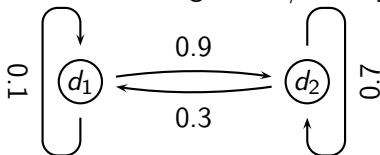

$$P_t(d_1) = P_{t-1}(d_1) * P_{11} + P_{t-1}(d_2) * P_{21}$$

$$P_t(d_2) = P_{t-1}(d_1) * P_{12} + P_{t-1}(d_2) * P_{22}$$

## Power method: Example

- What is the PageRank / steady state in this example?

- The steady state distribution (= the PageRanks) in this example are 0.25 for  $d_1$  and 0.75 for  $d_2$ . □

# Exercise: Compute PageRank using power method

# Solution

	$x_1$	$x_2$		
	$P_t(d_1)$	$P_t(d_2)$		
			$P_{11} = 0.7$	$P_{12} = 0.3$
			$P_{21} = 0.2$	$P_{22} = 0.8$
$t_0$	0	1	0.2	0.8
$t_1$	0.2	0.8	0.3	0.7
$t_2$	0.3	0.7	0.35	0.65
$t_3$	0.35	0.65	0.375	0.625
				...
$t_\infty$	0.4	0.6	0.4	0.6

PageRank vector =  $\vec{\pi} = (\pi_1, \pi_2) = (0.4, 0.6)$

$$P_t(d_1) = P_{t-1}(d_1) * P_{11} + P_{t-1}(d_2) * P_{21}$$

$$P_t(d_2) = P_{t-1}(d_1) * P_{12} + P_{t-1}(d_2) * P_{22}$$

# PageRank summary

- Preprocessing
  - Given graph of links, build matrix  $P$
  - Apply teleportation
  - From modified matrix, compute  $\vec{\pi}$
  - $\pi_i$  is the PageRank of page  $i$ .
- Query processing
  - Retrieve pages satisfying the query
  - Rank them by their PageRank
  - Return reranked list to the user

# PageRank issues

- Real surfers are not random surfers.
  - Examples of nonrandom surfing: back button, short vs. long paths, bookmarks, directories – and search!
  - → Markov model is not a good model of surfing.
  - But it's good enough as a model for our purposes.
- Simple PageRank ranking (as described on previous slide) produces bad results for many pages.
  - Consider the query [video service]
  - The Yahoo home page (i) has a very high PageRank and (ii) contains both *video* and *service*.
  - If we rank all Boolean hits according to PageRank, then the Yahoo home page would be top-ranked.
  - Clearly not desirable
- In practice: rank according to weighted combination of raw text match, anchor text match, PageRank & other factors
- → see lecture on Learning to Rank

# Example web graph

	PageRank	
$d_0$	0.05	
$d_1$	0.04	
$d_2$	0.11	
$d_3$	0.25	
$d_4$	0.21	
$d_5$	0.04	
$d_6$	0.31	
PageRank( $d_2$ ) < PageRank( $d_6$ ): why?		

	$a$	$h$
$d_0$	0.10	0.03

$d_4$	0.21	
$d_5$	0.04	
$d_6$	0.31	

PageRank( $d_2$ ) < PageRank( $d_6$ ): why?

	$a$	$h$
$d_0$	0.10	0.03
$d_1$	0.01	0.04
$d_2$	0.12	0.33
$d_3$	0.47	0.18

# How important is PageRank?

- Frequent claim: PageRank is the most important component of web ranking.
- The reality:
  - There are several components that are at least as important: e.g., anchor text, phrases, proximity, tiered indexes . . .
  - Rumor has it that PageRank in its original form (as presented here) now has a negligible impact on ranking!
  - However, variants of a page's PageRank are still an essential part of ranking.
  - Addressing link spam is difficult and crucial. □

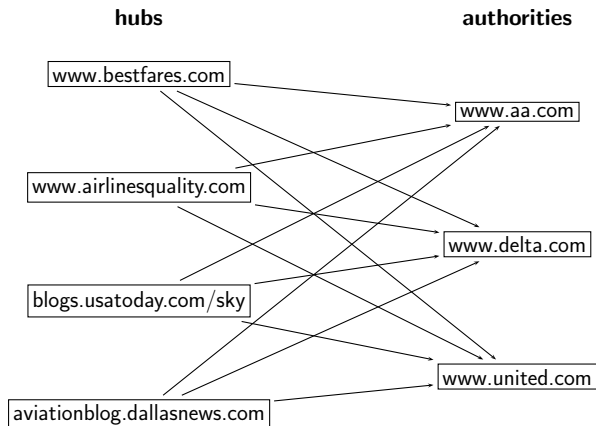

# HITS – Hyperlink-Induced Topic Search

- Premise: there are two different types of relevance on the web.
- Relevance type 1: **Hubs**. A hub page is a good list of [links to pages answering the information need].
  - E.g., for query [chicago bulls]: Bob's list of recommended resources on the Chicago Bulls sports team
- Relevance type 2: **Authorities**. An authority page is a direct answer to the information need.
  - The home page of the Chicago Bulls sports team
  - By definition: Links to authority pages occur repeatedly on hub pages.
- Most approaches to search (including PageRank ranking) don't make the distinction between these two very different types of relevance. □

# Hubs and authorities: Definition

- A good hub page for a topic **links to** many authority pages for that topic.
- A good authority page for a topic **is linked to** by many hub pages for that topic.
- Circular definition – we will turn this into an iterative computation. □

# Example for hubs and authorities

# How to compute hub and authority scores

- Do a regular web search first
- Call the search result the **root set**
- Find all pages that are linked by or link to pages in the root set
- Call this larger set the **base set**
- Finally, compute hubs and authorities for the base set (which we'll view as a small web graph) □

## Root set and base set (1)

The root set Nodes that root set nodes link to Nodes that link to root set nodes The base set

## Root set and base set (2)

- Root set typically has 200–1000 nodes.
- Base set may have up to 5000 nodes.
- Computation of base set, as shown on previous slide:
  - Follow outlinks by parsing the pages in the root set
  - Find  $d$ 's inlinks by searching for all pages containing a link to  $d$

# Hub and authority scores

- Compute for each page  $d$  in the base set a **hub score**  $h(d)$  and an **authority score**  $a(d)$
- Initialization: for all  $d$ :  $h(d) = 1$ ,  $a(d) = 1$
- Iteratively update all  $h(d), a(d)$
- After convergence:
  - Output pages with highest  $h$  scores as top hubs
  - Output pages with highest  $a$  scores as top authorities
  - So we output **two** ranked lists

# Iterative update

- For all  $d$ :  $h(d) = \sum_{d \mapsto y} a(y)$

- For all  $d$ :  $a(d) = \sum_{y \mapsto d} h(y)$

- Iterate these two steps until convergence

# Details

- Scaling
  - To prevent the  $a()$  and  $h()$  values from getting too big, can scale down after each iteration
  - Scaling factor doesn't really matter.
  - We care about the **relative** (as opposed to absolute) values of the scores.
- In most cases, the algorithm converges after a few iterations. □

# Hubs & Authorities: Comments

- HITS can pull together good pages regardless of page content.
- Once the base set is assembled, we only do link analysis, no text matching.
- Pages in the base set often do not contain any of the query words.
- In theory, an English query can retrieve Japanese-language pages!
  - If supported by the link structure between English and Japanese pages
- Danger: **topic drift** – the pages found by following links may not be related to the original query. □

# Proof of convergence

- We define an  $N \times N$  **adjacency matrix**  $A$ . (We called this the link matrix earlier.)
- For  $1 \leq i, j \leq N$ , the matrix entry  $A_{ij}$  tells us whether there is a link from page  $i$  to page  $j$  ( $A_{ij} = 1$ ) or not ( $A_{ij} = 0$ ).
- Example:

	$d_1$	$d_2$	$d_3$
$d_1$	0	1	0
$d_2$	1	1	1
$d_3$	1	0	0

# Write update rules as matrix operations

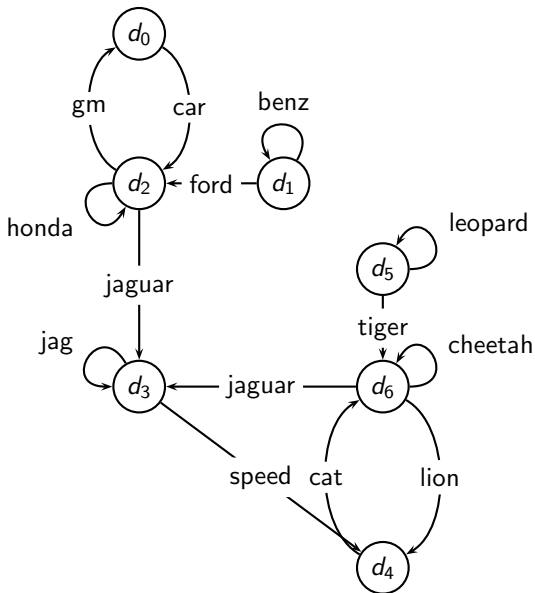

- Define the hub vector  $\vec{h} = (h_1, \dots, h_N)$  as the vector of hub scores.  $h_i$  is the hub score of page  $d_i$ .
- Similarly for  $\vec{a}$ , the vector of authority scores
- Now we can write  $h(d) = \sum_{y \rightarrow d} a(y)$  as a matrix operation:  
 $\vec{h} = A\vec{a} \dots$
- ... and we can write  $a(d) = \sum_{y \rightarrow d} h(y)$  as  $\vec{a} = A^T \vec{h}$
- HITS algorithm in matrix notation:
  - Compute  $\vec{h} = A\vec{a}$
  - Compute  $\vec{a} = A^T \vec{h}$
  - Iterate until convergence

# HITS as eigenvector problem

- HITS algorithm in matrix notation. Iterate:
  - Compute  $\vec{h} = A\vec{a}$
  - Compute  $\vec{a} = A^T\vec{h}$
- By substitution we get:  $\vec{h} = AA^T\vec{h}$  and  $\vec{a} = A^TA\vec{a}$
- Thus,  $\vec{h}$  is an eigenvector of  $AA^T$  and  $\vec{a}$  is an eigenvector of  $A^TA$ .
- So the HITS algorithm is actually a special case of the power method and hub and authority scores are eigenvector values.
- HITS and PageRank both formalize link analysis as eigenvector problems. □

# Example web graph

	PageRank	
$d_0$	0.05	
$d_1$	0.04	
$d_2$	0.11	
$d_3$	0.25	
$d_4$	0.21

# PageRank vs. HITS: Discussion

- PageRank can be precomputed, HITS has to be computed at query time.
  - HITS is too expensive in most application scenarios.
- PageRank and HITS make two different design choices concerning (i) the eigenproblem formalization (ii) the set of pages to apply the formalization to.
- These two are orthogonal.
  - We could also apply HITS to the entire web and PageRank to a small base set.
- Claim: On the web, a good hub almost always is also a good authority.
- The actual difference between PageRank ranking and HITS ranking is therefore not as large as one might expect. □

# Exercise

- Why is a good hub almost always also a good authority?

# Take-away today

- Anchor text: What exactly are links on the web and why are they important for IR?
- Citation analysis: the mathematical foundation of PageRank and link-based ranking
- PageRank: the original algorithm that was used for link-based ranking on the web
- Hubs & Authorities: an alternative link-based ranking algorithm

# Resources

- Chapter 21 of IIR
- Resources at <http://ifnlp.org/ir>
  - American Mathematical Society article on PageRank (popular science style)
  - Jon Kleinberg's home page (main person behind HITS)
  - A Google bomb and its defusing
  - Google's official description of PageRank: *PageRank reflects our view of the importance of web pages by considering more than 500 million variables and 2 billion terms. Pages that we believe are important pages receive a higher PageRank and are more likely to appear at the top of the search results.*
